Spain is Europe’s second largest producer of pork with 99,561 pig farms. The excess of manure available in intensive pig breeding areas in combination with lack of land to spread it on, needs addressing. Around 70 million kg of pig manure is produced daily in the country.

A variety of methods exists for slurry processing, although few can be considered as nutrient recovering processes or resource-efficient techniques. Currently, the solid fraction is dried or composted but little attention is paid to the liquid fraction which is considered to be “waste water” and can be expensive to treat. The liquid fraction is either applied directly to crops, left in lagoons to evaporate as much as possible or even illegally dumped into lakes or rivers. These processes cause an enormous environmental impact, increasing greenhouse emissions, polluting water reserves and soil.

1. Inefficient use of available organic resources in pig manure
2. Negative effects of extensive use of inorganic fertilizers
3. Unbalanced amount of phosphorus (P) in manure used for crop production.

In order to help to solve this problem, LIFE14/ENV/ES/00640 Smart Fertirrigation project foresees to demonstrate the environmental and economic feasibility of innovative pig manure treatment at pig farms in order to produce precise volumes of natural liquid fertilizers for direct injection into irrigation systems.

1. Apply an innovative treatment in order to recover the liquid fraction with its natural nutrients for direct injection into irrigation systems
2. Use of liquid fertilizer as a substitute for mineral fertilizers, reducing greenhouse gas emission and preventing soil acidification
3. Reduce the amount of P in the slurry by using new phytase enzymes in pig feed

In order to track our environmental problems and demonstrate the implementation of the integrated pig slurry treatment system, we implement different innovative technologies such as the use of fuzzy filter that will drastically decrease the amount of suspended solids in the liquid fraction. Innovative drying equipment considered to be a type of “green machine” will be implemented.

Expected results:
50% cost savings of liquid fertilizers vs inorganic fertilizer
70% substitution of inorganic fertilizers in the project area
Prevention of CO\textsuperscript{2} emissions vs inorganically fertilized fields
20% increase in nutrient absorption capacity of the plant vs inorganic fertilized fields, leading to
reduction of nitrogen and phosphorous in the ecosystem
30% reduction of phosphorus present in tested pig manure vs manure of conventionally bred pigs
